## EFFECTS OF CLIMATE ON MILITARY OPERATIONS

Extremely cold outbreaks during winter could have a serious impact on ground and air operations. During colder temperatures, hypothermia, frostbite, and cold-related injuries will slow the tempo of ground operations. Cold weather also impacts the turnaround time of aircraft, as maintenance, refueling, and ammunition loading are affected. Trafficability is favorably impacted by the state of the ground. The ground freezes around 10 November in the extreme north, around 20 December along the DMZ, and not until 30 January in the extreme south. Thawing begins around 30 January in Pusan, mid-February along the DMZ, and not until 20 March in the far north. Ice also impacts naval operations from December until March.

Rain is the biggest problem for military operations in Korea. Heavy rains during the Southwest Monsoon saturate the ground and make conditions ideal for flash flooding. Trafficability is impaired by the wet ground and the effects of suddenly changing shallow, slow moving streams into rapid, deep rivers. In addition, mountain passes and rough mountain terrain become even more difficult to traverse due to the rains.

General Information

1-44

Winter snows have an impact on aircraft takeoff/recovery at coastal bases and in mountainous terrain where snows are normally more significant. With limited highway LOCs available, heavier snowfalls can cause a significant impact on supply/resupply operations. The worst flying weather of the year occurs during the summer rainy season. About half the season, ceilings and visibilities are less than 3,000 ft and 3 mi, respectively.

In determining the effect of surface winds, direction is the most significant criteria. During the Northwest Monsoon (November-March), the effects of nuclear, biological, and chemical (NBC) warfare to the south are heightened. Although temperatures modify the effect of NBC agents at this time, dispersion patterns would be favorable for North Korean use. The Southwest Monsoon (June-September) has temperatures and humidity favorable to North Korean NBC use, but dispersion patterns are less favorable. The Southwest Monsoon pattern also has periods of strong wind speeds which may adversely affect air operations, air defense, and communications, which are antenna-dependent.

The best period for air and ground observation is the generally clear winter period, December through March. Flying weather in the winter is the best of any time of the year, although pilots must take note of frequent severe turbulence and icing. Both hazards can be associated with the passage of a trough. The fall period, October through November, permits good air and ground observation; however, air operations are frequently marginal during morning hours due to periods of ground fog in river valleys and low-lying areas. During the spring, April through June, air and ground observation are often limited as a result of increasing cloud cover and precipitation. Additionally, the spring period brings with it an increase in early morning fog that burns off by late morning. Also during the spring, dust resulting from Yellow Wind can reduce visibility at times to less than 1 mile, affecting both ground and air observation. Periods of rain during the summer, when the peninsula receives the majority of its annual precipitation in the form of monsoons, greatly reduce air and ground observation capability.

## VEGETATION

During World War II and the Korean War, the Korean Peninsula was nearly deforested. As a result, only scrub tree growth and relatively young forests exist. Areas not classified as cultivated or built-up are generally categorized as forests. Areas that contain trees over 6.1 m (20 ft) occupy only onethird of South Korea and are usually dense with tightly spaced trees that are generally less than 10 m (33 ft) tall. In these forests, maneuvering vehicles is difficult because trees are so closely spaced. The valley floors are consistently terraced and planted with rice crops, assuming that adequate supplies of water are available for these terraced fields. Low, dry crops are planted where adequate supplies of water are not available, usually on the edges of valleys. The terrain and climate conditions of Korea are favorable for growth of coniferous forest including pine, fir, larch, and spruce trees. In the past, most of the forest land on the peninsula has been denuded, and the only remaining mature natural forests are on the higher mountains, particularly in the north. Most of the peninsula's woodlands are 20- to 30-year-old scrub deciduous forests. The central regions have a mixed cover of hardwoods and conifers. but near urban areas the forests have virtually disappeared. In

the southern portion, scattered stands of bamboo and pine are found among the generally deciduous growth.

## EFFECTS OF VEGETATION ON MILITARY OPERATIONS

Because large stands of trees and forests are virtually nonexistent, except for remote mountainous areas in the northern half of the peninsula, vegetation will have little impact on observation and fields of fire.

The concealment afforded by vegetation is generally good year round, but is restricted mainly to evergreen trees in mountainous areas. As operations move north into the more mountainous terrain, concealment increases. Concealment for ground troops is fair in areas of cultivation, mainly in rice paddies and orchards, but these are seasonal except in dykes and ditches. Concealment, especially aerial, is limited in the young forests throughout Korea.

## SURFACE MATERIALS

The predominant surface material throughout the peninsula is sand composed of rocks and silt. The soil cover is usually thin outside the valleys, on hills, and on mountains. In the valleys, natural soils are normally thick sands, and silty sands with considerable cobble-size rock in the upper reaches of the valleys. In the wide valleys of the western portion of the peninsula, minimal rock is present in the natural soil. Cultivated soils, especially in terraced rice paddies, are artificially developed through regular plowing, irrigating, and fertilizing over long periods. Settling of silts from annual irrigation and also from occasional flooding of rivers has changed the soil composition from its original character. In most areas, rice paddy soil is a uniform silty-loam, which is totally unlike the natural soils in the vicinity. During spring planting, these soils are usually supersaturated to allow an easy transition for the transplanting of rice seedlings. introduction of this moisture in the spring and constant flooding throughout most of the summer months make these fields impossible for off-road movement of even the lightest motor vehicles. During early fall, these rice paddies are

drained to allow for the rice harvest and for the turning of the soil for nutrient retention. The turning of the soil allows the ground to dry and become hard enough for some trafficability.
